

Lecture 1 : Calculus

Piotr Zwiernik

Mathematics Brush-up

Goal of the course

Review core tools of calculus that power modern economics, finance, and data-driven policy.

These tools are crucial in courses on micro/macro, econometrics, finance, and machine learning.

Warm up before the Master starts: sharpen intuition, not just technique.

Main references:

Welcome to Our Class Q&A Forum!

Purpose: A Space for Collaborative Learning

This forum is our dedicated space for all questions related to course content. It's a place for you to ask for help and to help your classmates.

How to Access

1. Go to the **Classwork** tab.
2. Find the topic "**Student Q&A Forum**".
3. Click on the question thread to view discussions or ask your own!

Your Role & My Role

Your Role: Be Active!

- **Ask:** Don't hesitate to post a question.
- **Answer:** If you know the answer to a classmate's question, please reply!

My Role: Facilitator

- I will check the forum 2-3 times a day to guide discussions and answer questions that remain open.

Cultivate a Critical Mindset

Technical knowledge requires effort.

- **If a step feels “magical”, stop.** Ask *why* it works, not just *how*.
- **Challenge every answer — especially given by LLMs.**

Large-language models can sound confident yet be wrong; verify with first principles or a textbook.

- **Use multiple lenses.**
Check special cases, sketch a graph, test numerically, or search for a counterexample.

Index

1. Sequences and series
2. Functions of one variable
3. Differentiation
4. Integration
5. Vectors
6. Matrices and determinants
7. Systems of linear equations
8. Eigenvalue problems and quadratic forms
9. Functions of several variables
10. Introduction to differential equations

Sequences

A **sequence** is an ordered list of real numbers (a_1, a_2, \dots) indexed by $n \in \mathbb{N}$.

Notation: $\{a_n\}_{n=1}^{\infty}$ where each $a_n \in \mathbb{R}$.

Define by a **formula** or a **recursion**.

Examples:

1. $a_n = \frac{n-1}{2n+1}$ ($a_1 = 0, a_2 = \frac{1}{5}, a_3 = \frac{2}{7}, \dots$)
2. $a_1 = 2, a_{n+1} = 2a_n - 1$ ($2, 3, 5, 9, \dots$)
3. $a_1 = 1, a_2 = 1, a_{n+1} = a_n + a_{n-1}$ (Fibonacci)
4. **Arithmetic:** $a_n = a_1 + (n-1)d$
5. **Geometric:** $a_n = a_1 r^{n-1}$

Why sequences show up in modern econ/data

Where they appear:

- **User metrics:** daily active users (DAU) over days n .
- **Inflation tracking:** monthly CPI/CPIH index a_n .
- **Training loss:** $a_n = \text{loss after } n \text{ gradient steps}$ (decreasing sequence).
- **Carbon budgets:** remaining allowance after n years.

Read Ch. 2 Werner-Sotskov. Exercises: 2.4, 2.5, 2.7 (Werner-Sotskov)

Small motivating examples

1. **EAR vs APR in FinTech.** Let P be the initial investment. If a platform advertises an *annual percentage rate* (APR) R but compounds m times/year, then after n years:

$$a_n = P \left(1 + \frac{R}{m}\right)^{mn}.$$

The one-year *effective annual rate* (EAR) is:

$$\left(1 + \frac{R}{m}\right)^m - 1.$$

(APR is the quoted yearly rate without compounding; APY/EAR accounts for compounding.)

2. **Creator economy revenue.** If the number of views per video is v_n and the cost-per-thousand views (*CPM*) is c , total revenue over n videos is:

$$s_n = \sum_{k=1}^n c v_k.$$

Properties of a sequence

A sequence is **increasing** if $a_{n+1} \geq a_n$ (strictly if $>$).

Decreasing if $a_{n+1} \leq a_n$ (strictly if $<$).

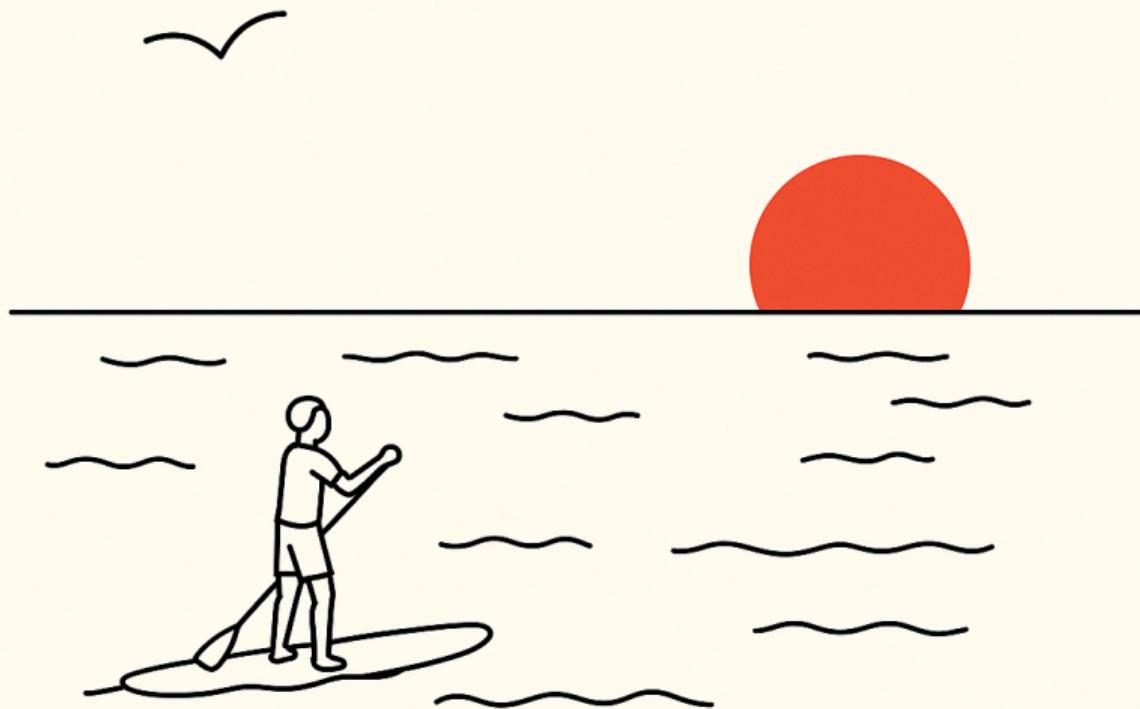

Monotone if increasing or decreasing.

Bounded if $\exists C > 0$ s.t. $|a_n| \leq C$ for all n .

Examples:

1. $a_n = 2(n - 1)^2 - n$ is strictly increasing (since $a_{n+1} - a_n = 4n - 3 > 0$)
2. $a_n = 1/n^2$ is bounded ($0 < a_n \leq 1$)
3. **Training loss:** if a learning rate is sensible, $a_n = \text{loss}$ often decreases and is bounded below by 0 \Rightarrow convergent in many practical cases.

Can a strictly increasing sequence be bounded?

Limit of a sequence

A real number a is the **limit** of $\{a_n\}$ if as $n \rightarrow \infty$, a_n gets arbitrarily close to a . Notation:
 $\lim_{n \rightarrow \infty} a_n = a$.

A sequence is **convergent** if it has a limit; otherwise it **diverges**.

Examples

1. $a_n = \frac{1}{n^2} \rightarrow 0$
2. $a_n = (-1)^n$ has no limit
3. $a_n = n^2 \rightarrow \infty$
4. $a_n = r^n \rightarrow 0$ if $|r| < 1$; diverges if $r > 1$; no limit if $r \leq -1$.

Epsilon-definition

Definition: $a = \lim_{n \rightarrow \infty} a_n$

$$\forall \epsilon > 0 \quad \exists N_\epsilon \quad \text{s.t.} \quad \forall n > N_\epsilon : \quad |a_n - a| < \epsilon.$$

Example: $a_n = \frac{1}{n} \rightarrow 0$. For any $\epsilon > 0$, take $N_\epsilon > \frac{1}{\epsilon}$.

Checks:

- $\lim a_n = a$ if and only if $\lim |a_n - a| = 0$.
- If $a_n = a$ for all n , then $\lim a_n = a$.

If formal definition hard to work with, try to squeezing with easier bounds

If $0 < \frac{1}{2n^2-1} \leq \frac{1}{n}$ for $n \geq 1$, then $\lim \frac{1}{2n^2-1} = 0$.

Limits that matter in practice

Classics

1. $\left(1 + \frac{1}{n}\right)^n \rightarrow e$
2. $\left(1 + \frac{x}{n}\right)^n \rightarrow e^x$ for any real x

Continuous compounding & APY: if APR is R , then

$$\lim_{m \rightarrow \infty} \left(1 + \frac{R}{m}\right)^m = e^R, \quad \text{EAR} = e^R - 1.$$

Example: APR = 8% \Rightarrow EAR \approx 8.329%.

Monotone convergence and algebra of limits

Theorem

Every bounded monotone sequence is convergent.

(Just bounded or just monotone is not enough in general)

Example: the sequence $a_1 = 1$, $a_{n+1} = \sqrt{3a_n}$ is bounded by 3 (proof by induction) and strictly increasing (since $\frac{a_{n+1}}{a_n} > 1$), thus convergent.

Algebra of limits

If $\lim a_n = a$ and $\lim b_n = b$, then

$$\lim(a_n + b_n) = a + b, \quad \lim(a_n b_n) = ab, \quad \lim \frac{a_n}{b_n} = \frac{a}{b} \text{ if } b_n, b \neq 0.$$

Partial sums and series

The n th partial sum s_n of $\{a_n\}$ is

$$s_n = \sum_{k=1}^n a_k.$$

Examples

1. Arithmetic sequence $a_n = a_1 + (n - 1)d$: $s_n = na_1 + \frac{n(n - 1)}{2}d$
2. Geometric sequence $a_n = a_1 r^{n-1}$, $r \neq 1$: $s_n = a_1 \frac{1 - r^n}{1 - r}$

Use-cases:

- Let *margin* be the profit earned per customer per period and p be the customer retention rate. The total profit from a single customer over n periods is: $s_n = \sum_{k=1}^n \text{margin} \cdot p^k$.
- Let E_k be the emissions produced in period k (e.g., in tonnes of CO₂). Then the total emissions over n periods are: $s_n = \sum_{k=1}^n E_k$, which can be compared to a fixed carbon budget.

Series and convergence

A **series** is the limit (if it exists) of partial sums:

$$\sum_{k=1}^{\infty} a_k := \lim_{n \rightarrow \infty} s_n.$$

Geometric series: converges if and only if $|r| < 1$ with

$$\sum_{k=1}^{\infty} a_1 r^{k-1} = \frac{a_1}{1 - r}.$$

Customer Lifetime Values: Consider the example on the previous slide. With margin m and monthly retention $p < 1$, discounted at monthly rate d ,

$$\text{CLV} = \sum_{k=1}^{\infty} \frac{m p^k}{(1 + d)^k} = \frac{m \frac{p}{1+d}}{1 - \frac{p}{1+d}} = \frac{mp}{1 + d - p}.$$

Chapter 2: Functions of one variable

A **one-variable function** assigns a unique $y \in \mathbb{R}$ to each $x \in \mathbb{R}$: $y = f(x)$.

x : independent (exogenous) variable; y : dependent (endogenous) variable.

Examples in econ/data: cost, revenue, demand, utility, probability of purchase vs. price, click-through rate vs. ad spend, etc.

Read Ch. 3 Werner-Sotskov; Simon-Blume 2.1-2.2, 5.1-5.3.

Graph and domain

Definition

The graph of f is $\{(x, y) \in \mathbb{R}^2 : y = f(x)\}$.

The domain D is the set of x where $f(x)$ is defined.

Notation: $f : D \rightarrow \mathbb{R}$.

Example: $f(x) = \frac{1}{x}$ has $D = \mathbb{R} \setminus \{0\}$.

Sometimes we restrict the domain (e.g., prices $x \geq 0$).

Properties of functions

A function $f : D \rightarrow \mathbb{R}$ is **increasing** if $f(x_1) \leq f(x_2)$ for any $x_1 < x_2$ in D (strict if $<$).

Decreasing: reverse inequality.

Bounded: $\exists C > 0$ s.t. $|f(x)| \leq C$ for all $x \in D$.

Examples:

- **Price-demand curve** often decreasing on realistic intervals.
- **Learning curve** (error vs. epochs) typically decreasing and bounded below by 0.

Convex/concave functions

For $x_1 < x_2$ and $t \in [0, 1]$, the **convex combination** is $tx_1 + (1 - t)x_2$.

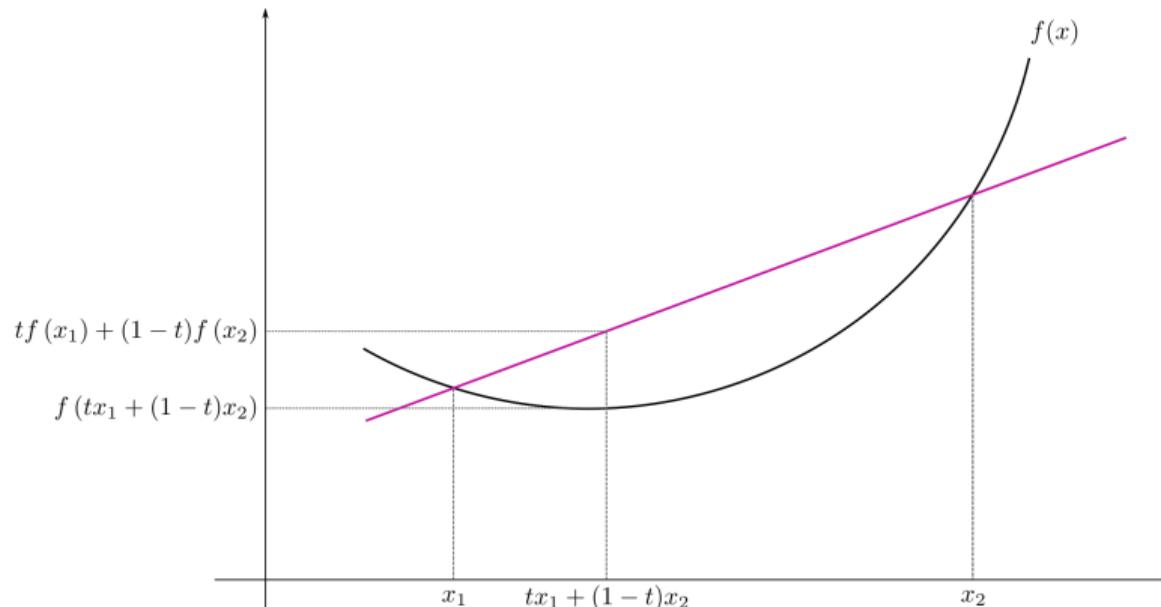

A set $D \subset \mathbb{R}$ is **convex** if it contains convex combinations.

A function $f : D \rightarrow \mathbb{R}$ on convex D is **convex** if

$$f(tx_1 + (1 - t)x_2) \leq tf(x_1) + (1 - t)f(x_2)$$

(and **concave** if \geq). Strict versions replace \leq by $<$ for $t \in (0, 1)$ and $x_1 \neq x_2$.

Convex function

Quasi-convex/concave functions

f is quasi-convex if

$$f(tx_1 + (1 - t)x_2) \leq \max\{f(x_1), f(x_2)\}.$$

Quasi-concave if $\geq \min\{f(x_1), f(x_2)\}$.

Facts: convex \Rightarrow quasi-convex; concave \Rightarrow quasi-concave.

Any strictly increasing function is both quasi-convex and quasi-concave.

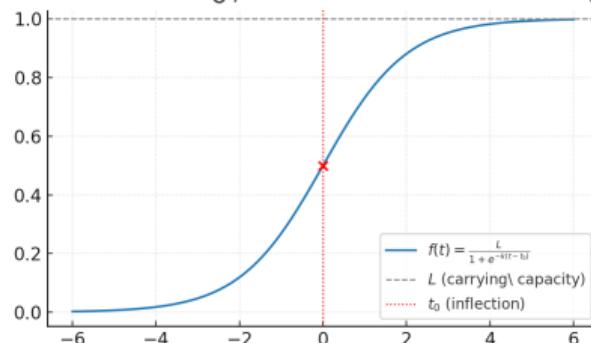

Economic examples: Indifference curves are typically quasi-convex; profit in price can be quasi-concave on feasible ranges.

Economic example: logistic growth (adoption curves)

The logistic function

$$f(t) = \frac{L}{1 + e^{-k(t-t_0)}}$$

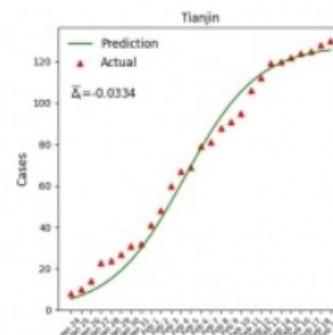

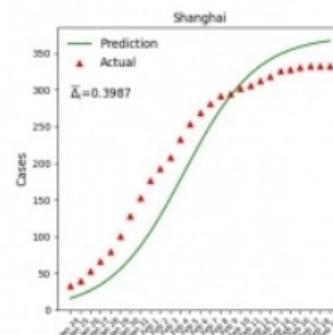

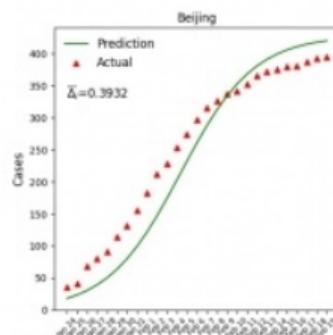

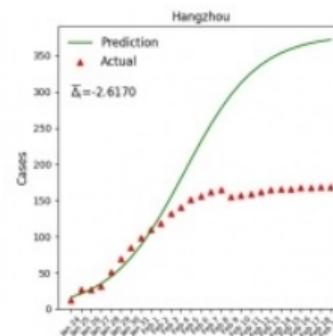

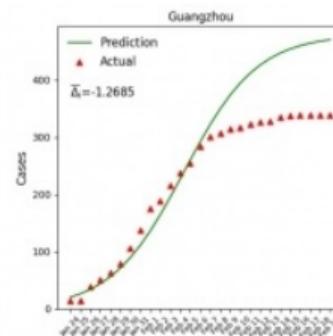

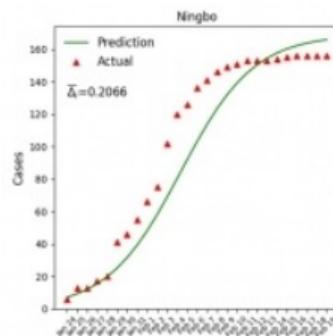

models technology/product adoption or viral spread. Early exponential growth, mid-phase inflection at t_0 , saturation near L (market size).

Interpretation: growth accelerates, then slows as saturation/frictions (capacity, regulation, budgets) bind. Same shape often appears in learning curves (accuracy vs. data).

Epidemics and beyond

Logistic curves fit epidemic growth, but also market penetration, platform adoption, content diffusion. Check the following epidemic curves over time of the COVID-19 in China

Examples of functions

1. Monomials: $f(x) = ax^k$
2. Polynomials: sums of monomials
3. Rational: ratios of polynomials
4. Exponential: $f(x) = a^x$
5. Trig: $\sin x, \cos x, \dots$
6. Linear: $f(x) = mx + b$ (slope m , intercept b ; also $y - f(x_0) = m(x - x_0)$)
7. Natural exponential: $f(x) = e^x$ ($e^x = \lim_n (1 + \frac{x}{n})^n$)
8. Natural log: $f(x) = \log x$ ($e^{\log x} = x, \log(e^x) = x$)

Econ view: demand curves (often decreasing), cost curves (often convex), utility (often concave), isoelastic forms, log-sum-exp in discrete choice.

Exponential functions

$$f(x) = 1^x$$

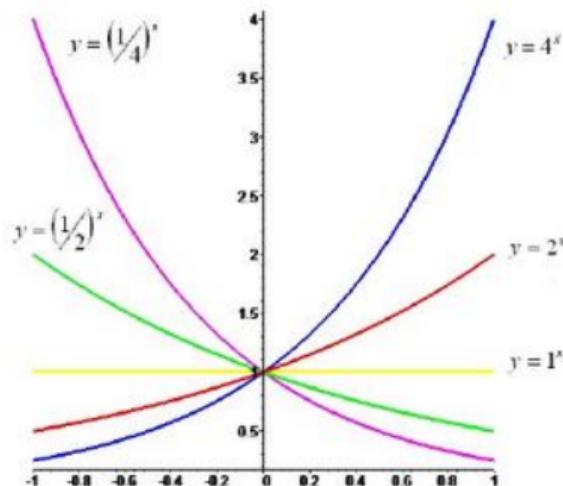

Horizontal line with y-intercept 1

$$f(x) = a^x, \quad 0 < a < 1$$

Exponential decay

$$f(x) = a^x, \quad a > 1$$

Exponential growth

Chapter 3: Differentiation

Differentiation measures sensitivity: how $f(x)$ changes with small changes in x .

Examples: price → demand sensitivity, ad spend → clicks, carbon tax → emissions, risk → portfolio value.

Calculus also underpins extrema, monotonicity, convexity — and the local behavior behind optimization and ML.

Read Ch. 4 Werner-Sotskov; Simon-Blume Chs. 2-5.

Exercises: 4.6(c), 4.10, 4.14, 4.15(a)-(c), 4.16(d), 4.17(b) (Werner-Sotskov), 5.5 (b)-(c)-(e) (Simon-Blume)

Limit of a function

Let $f : D \rightarrow \mathbb{R}$ and $x_0 \in \mathbb{R}$. $L = \lim_{x \rightarrow x_0} f(x)$ if for any sequence $x_n \in D$ with $x_n \rightarrow x_0$, we have $f(x_n) \rightarrow L$.

Remark: x_0 need not be in D (removable/essential discontinuities matter in econ too).

Example: $\lim_{x \rightarrow 0} x \sin \frac{1}{x} = 0$ since $0 \leq |x \sin \frac{1}{x}| \leq |x|$.

Algebra of limits

If $\lim f = y_1$ and $\lim g = y_2$ at x_0 , then

$$\lim(f + g) = y_1 + y_2, \quad \lim(fg) = y_1y_2, \quad \lim \frac{f}{g} = \frac{y_1}{y_2} \text{ if } y_2 \neq 0, g \neq 0 \text{ near } x_0.$$

Continuity

Definition

f is **continuous** at $x_0 \in D$ if $\lim_{x \rightarrow x_0} f(x) = f(x_0)$. If f is continuous at every point of $B \subset D$, we say f is continuous on B .

Theorem: If f, g are continuous at x_0 then so are $f + g$ and fg . If moreover, $g(x) \neq 0$ around x_0 , then $\frac{f}{g}$ is continuous at x_0 .

Heine-Borel fact (1D): continuous $f : [a, b] \rightarrow \mathbb{R}$ is bounded.

Composition and inverse

Two important results

(composition) If f, g are continuous, so is $h = g \circ f$; moreover

$$\lim_{x \rightarrow x_0} g(f(x)) = g\left(\lim_{x \rightarrow x_0} f(x)\right).$$

(inverse) If $f : [a, b] \rightarrow \mathbb{R}$ is strictly monotone and continuous with $f(a) = c, f(b) = d$, then the inverse $f^{-1} : [c, d] \rightarrow [a, b]$ is also strictly monotone and continuous.

Econ: Let p denote the price of a good and q the quantity sold. The *demand function* $q(p)$ gives the quantity q consumers will buy at price p . Equivalently, the *inverse demand function* $p(q)$ gives the price at which q units can be sold. Revenue as a function of quantity is:

$$R(q) = p(q) \cdot q,$$

which involves compositions.

Derivative

Let $f : (a, b) \rightarrow \mathbb{R}$. f is **differentiable** at x if

$$\lim_{h \rightarrow 0} \frac{f(x + h) - f(x)}{h}$$

exists. Denote this limit by $f'(x)$.

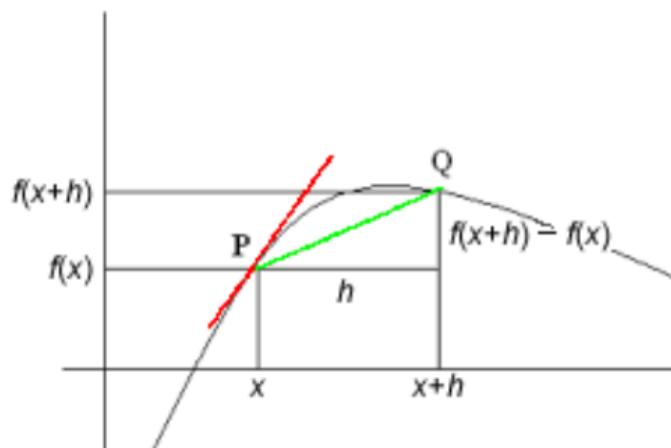

Fact: differentiable \Rightarrow continuous (not conversely: $|x|$ is continuous but not differentiable at 0).

Interpretation: local linear approximation — crucial in marginal analysis, price elasticity, and gradient-based optimization.

Geometric interpretation

If f is differentiable at x_0 , the tangent line at $(x_0, f(x_0))$ is

$$y = f(x_0) + f'(x_0)(x - x_0).$$

slope of **secant** through P,Q: $\frac{f(x+h)-f(x)}{h}$; slope of **tangent** at P: $f'(x)$

A “marginal” is a derivative

In economics, a **marginal** quantity measures how much something changes when we increase an input by a small amount. Mathematically, we often approximate

$$f(x + 1) - f(x) \approx f'(x),$$

when the change is 1 unit.

Examples:

- **Marginal revenue:** $\frac{d}{dq}[p(q)q]$ at the current sales level q . The derivative tells you how much extra revenue you gain (or lose) by selling one more unit.
- **Click-through sensitivity:** $\frac{d \text{CTR}}{d(\text{ad spend})}$ at the budget currently in use. Here CTR (click-through rate) is a function of ad spending; the derivative measures how much CTR improves with an extra euro of spending.

If the change is Δx rather than 1: $f(x + \Delta x) - f(x) \approx f'(x) \Delta x$.

In differential notation: $df \approx f'(x) dx$

Derivatives of elementary functions

1. $c' = 0$
2. $(x^n)' = nx^{n-1}$ for $n \in \mathbb{N}$
3. $(x^\alpha)' = \alpha x^{\alpha-1}$ for $\alpha \in \mathbb{R}$, $x > 0$
4. $(\log x)' = \frac{1}{x}$, $x > 0$
5. $(\sin x)' = \cos x$
6. $(\cos x)' = -\sin x$
7. $(e^x)' = e^x$
8. $(a^x)' = a^x \log a$, $a > 0$

Proof of 8: $(a^x)' = (e^{x \log a})' = a^x \log a$ (chain rule)

Product/quotient rules

If f, g are differentiable:

- $(f + g)' = f' + g'$
- $(fg)' = f'g + g'f$ [Leibniz rule]
- $\left(\frac{f}{g}\right)' = \frac{f'g - g'f}{g^2}$ where $g \neq 0$ near the point.

Example (revenue): $R(q) = p(q)q$, then $R'(q) = p'(q)q + p(q)$.

Chain rule

If $h = g \circ f$ and f, g are differentiable at the relevant points, then

$$h'(x) = g'(f(x)) f'(x).$$

Example (cost of production):

$$C(x) = 4 + \log(x+1) + \sqrt{3x+1} \Rightarrow C'(x) = \frac{1}{x+1} + \frac{3}{2\sqrt{3x+1}}.$$

Example (choice models): In discrete choice models, the logistic function $\sigma(x) = \frac{1}{1+e^{-x}}$ maps a score x (reflecting how attractive an option is) to the probability of choosing it. Its derivative $\sigma'(x) = \sigma(x)[1 - \sigma(x)]$ measures how sensitive the choice probability is to changes in x .

Differentiating $u(x)^{v(x)}$

Let $u(x) > 0$. For $h(x) = u(x)^{v(x)}$, taking logs gives:

$$\log h = v \log u \quad \Rightarrow \quad \frac{h'}{h} = v' \log u + v \frac{u'}{u}.$$

Hence

$$h'(x) = u(x)^{v(x)} \left(v'(x) \log u(x) + v(x) \frac{u'(x)}{u(x)} \right)$$

Econ example: A startup's valuation is $V(t) = V_0[1 + g(t)]^{T(t)}$, where $g(t)$ is the projected annual growth rate and $T(t)$ the number of years that growth lasts. Both $g(t)$ and $T(t)$ vary with t .

Some of the contributors (in form of *caganers*)

Newton

Leibniz

Euler

Lagrange

Derivative of the inverse

Theorem: If f is strictly monotone, continuous, and differentiable at x with $f'(x) \neq 0$, then f^{-1} is differentiable at $y = f(x)$ and

$$(f^{-1})'(y) = \frac{1}{f'(x)} = \frac{1}{f'(f^{-1}(y))}.$$

Since $f^{-1}(f(x)) = x$, chain rule gives $(f^{-1})'(f(x))f'(x) = 1$.

Example: $f(x) = e^x \Rightarrow (\log)'(y) = 1/y$.

Higher-order derivatives: If f' is differentiable, its derivative is called the **second derivative** of f and denoted f'' . Similarly, we can define **higher-order derivatives**, and $f^{(n)}$ is called the n th derivative of f . If $f^{(n)}$ is continuous, we say that f is n times **continuously differentiable** or **C^n** for short.

L'Hôpital's rule

Theorem: Let f, g be C^1 on (a, b) with $g' \neq 0$ on (a, b) . If

$$\lim_{x \rightarrow x_0} f(x) = \lim_{x \rightarrow x_0} g(x) = 0 \quad \text{or} \quad \pm\infty,$$

then

$$\lim_{x \rightarrow x_0} \frac{f(x)}{g(x)} = \lim_{x \rightarrow x_0} \frac{f'(x)}{g'(x)} \quad (\text{if the RHS limit exists}).$$

Proof idea uses the Mean Value Theorem (slide 54).

Example:

$$\lim_{x \rightarrow 0} (1+x)^{1/x} = \exp\left(\lim_{x \rightarrow 0} \frac{\log(1+x)}{x}\right) = \exp\left(\lim_{x \rightarrow 0} \frac{1}{1+x}\right) = e.$$

Monotonicity via derivatives

If f is differentiable on (a, b) :

1. f increasing on $[a, b] \iff f'(x) \geq 0$ on (a, b) .
2. f decreasing on $[a, b] \iff f'(x) \leq 0$ on (a, b) .
3. f constant on $[a, b] \iff f'(x) = 0$ on (a, b) .
4. $f'(x) > 0$ on $(a, b) \Rightarrow f$ strictly increasing on $[a, b]$.
5. $f'(x) < 0$ on $(a, b) \Rightarrow f$ strictly decreasing on $[a, b]$.

Converse of 4-5 can fail at isolated points (e.g., x^3).

Example: $f(x) = \frac{x^3}{3} + 2x^2 + 3x + 1$; $f'(x) = (x+1)(x+3)$ determines monotonicity intervals and local extrema.

Optimal points: first-order conditions

Local optima

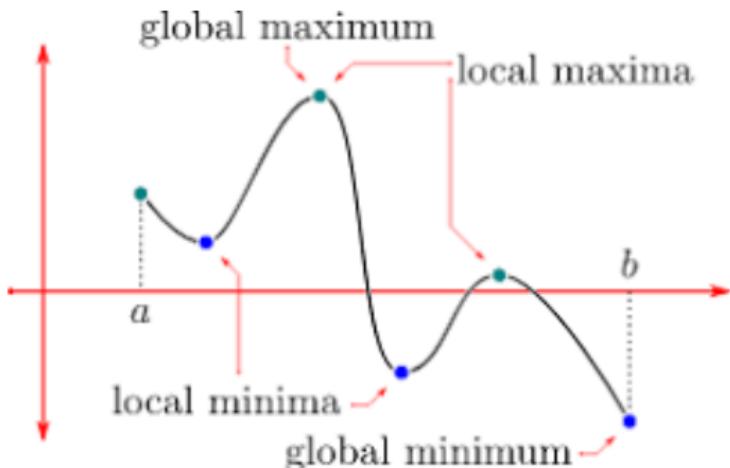

Let $f : D \rightarrow \mathbb{R}$. A point $x_0 \in D$ is a **local max** if $\exists (a, b) \subset D$ with $x_0 \in (a, b)$ and $f(x) \leq f(x_0)$ for all $x \in (a, b)$. Similarly for **local min** with \geq .

If f has a local optimum at interior x and is differentiable, then $f'(x) = 0$ (**necessary**, not sufficient).

Economic flavor: In profit maximization, the optimal quantity q^* often satisfies the first-order condition $f'(q^*) = 0$, which, for profit $\pi(q) = R(q) - C(q)$, means *marginal revenue* $R'(q)$ equals *marginal cost* $C'(q)$.

If x is stationary ($f'(x) = 0$) and f is strictly increasing to the left and strictly decreasing to the right, then x is a local max (reverse for min).

Optimal points

Example: Timing a sale (present value)

Suppose an assets market value is $V(t)$ at time t . At a constant annual interest rate R , the **present value** of selling at time t is

$$P(t) = V(t) e^{-Rt},$$

where e^{-Rt} discounts future cash flows.

Goal: Choose t to maximize $P(t)$.

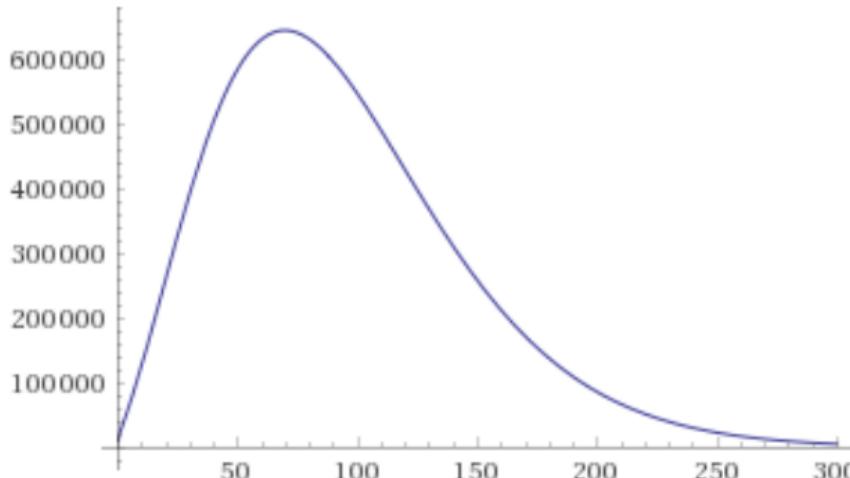

FOC (set derivative to zero):

$$P'(t) = V'(t)e^{-Rt} - R V(t)e^{-Rt} = 0 \quad \Rightarrow \quad \frac{V'(t)}{V(t)} = R.$$

Interpretation: Sell when the assets *instantaneous percentage growth rate* (matches) the *interest rate you could earn in the bank*.

Example: If $V(t) = 10000 e^{\sqrt{t}}$ and $R = 6\%$, then $P(t) = 10000 e^{\sqrt{t}-0.06t}$, which is maximized near $t \approx 69.44$.

Plot of the present value $P(t)$

`plot 10000 e^{\sqrt{t} - 0.06t} from 0 to 300`

Computed by Wolfram|Alpha

To certify a **global** optimum on an interval, compare values at boundaries and critical points.
Here $P(0) = 10000$, $\lim_{t \rightarrow \infty} P(t) = 0$.

Second-order conditions

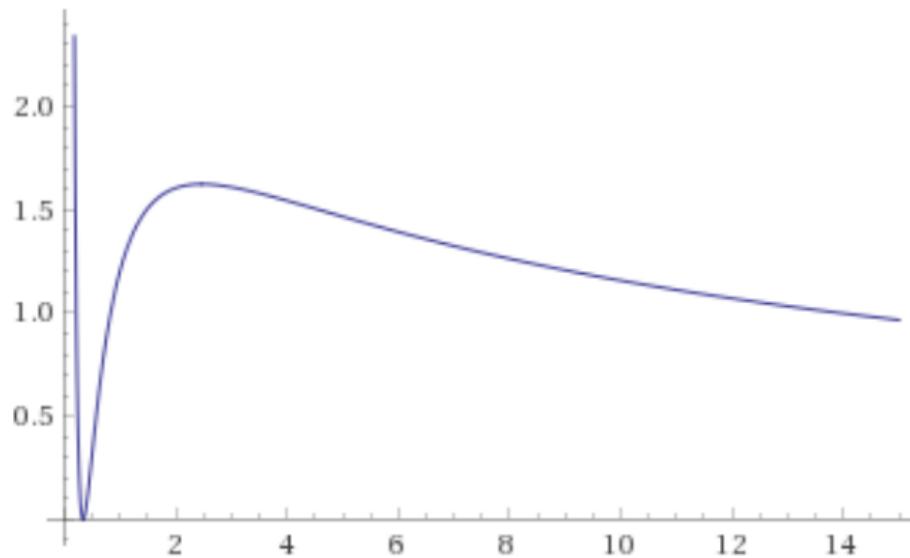

Test: If $f'(x_*) = 0$ and $f''(x_*) < 0 (> 0)$, then x_* is a strict local max (min). Higher-order tests extend this when $f''(x_*) = 0$.

Example: For $f(x) = \frac{\log^2(3x)}{x}$ ($x > 0$):

$$f'(x) = \frac{(2 - \log 3x) \log 3x}{x^2}, \quad f''(x) = \frac{2(1 - 3 \log 3x + \log^2 3x)}{x^3}.$$

Critical points at $x_1 = \frac{1}{3}$ (min), $x_2 = \frac{e^2}{3}$ (max).

Plot of $f(x) = \frac{\log^2 3x}{x}$, $x > 0$

plot $\ln^2(3x)/x$ from 0 to 15 | Computed by Wolfram|Alpha

$\lim_{x \rightarrow \infty} f(x) = 0$, $\lim_{x \rightarrow 0^+} f(x) = \infty$, $f(x_1) = 0$, $f(x_2) > 0 \Rightarrow x_1$ global min, no global max.

Convexity and concavity

If f is twice differentiable on (a, b) :

1. f convex on $[a, b] \Leftrightarrow f''(x) \geq 0$ for all $x \in (a, b)$.
2. f concave on $[a, b] \Leftrightarrow f''(x) \leq 0$ for all $x \in (a, b)$.
3. $f'' > 0 (< 0) \Rightarrow f$ strictly convex (concave).

Theorem: If f and g are convex (or concave), then $f \circ g$ is convex (or concave).

Example: $f(x) = e^{x^2}$ is strictly convex on $[0, \infty)$.

Economics: costs often convex; utility often concave; regularized losses in ML are designed to be convex for tractable optimization.

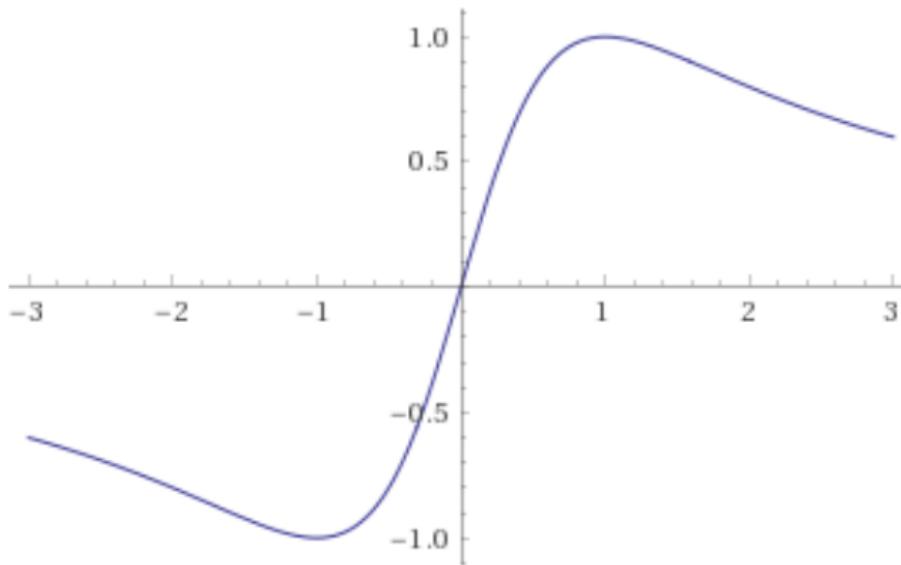

Example of changing curvature

Let $f(x) = \frac{2x}{x^2 + 1}$. Then

$$f'(x) = \frac{2(1 - x^2)}{(x^2 + 1)^2}, \quad f''(x) = \frac{4(x^3 - 3x)}{(x^2 + 1)^3}.$$

So f is strictly convex on $[-\sqrt{3}, 0] \cup [\sqrt{3}, \infty)$ and strictly concave on $(-\infty, -\sqrt{3}] \cup [0, \sqrt{3}]$.

$$\text{Plot of } f(x) = \frac{2x}{x^2 + 1}$$

plot $2x/(x^2+1)$ from -3 to 3 | Computed by Wolfram|Alpha

Inflexion points at $x \in \{-\sqrt{3}, 0, \sqrt{3}\}$. Global max at $x = 1$, min at $x = -1$, and $\lim_{|x| \rightarrow \infty} f(x) = 0$.

Inflexion points

If f is C^n on (a, b) , an **inflexion point** at x_* occurs when curvature changes sign. A sufficient test:

$$f''(x_*) = \dots = f^{(n-1)}(x_*) = 0, \quad f^{(n)}(x_*) \neq 0, \quad n \text{ odd.}$$

Example: $f(x) = x^3$ has $f''(0) = 0$, $f^{(3)}(0) = 6 \neq 0 \Rightarrow$ inflexion at 0.

Mean-value theorem

Mean Value Theorem

If f is continuous on $[a, b]$ and differentiable on (a, b) , then $\exists c \in (a, b)$ such that

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad (\text{equivalently } f(b) = f(a) + f'(c)(b - a)).$$

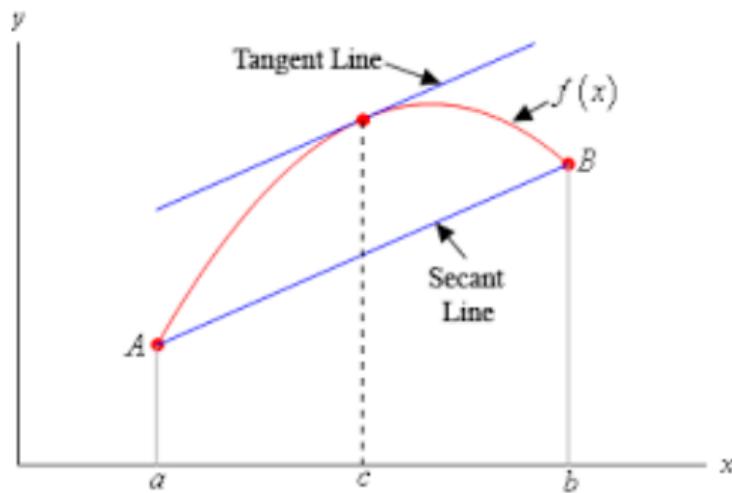

Proof idea: consider $h(x) = (f(b) - f(a))x - (b - a)f(x)$; since $h(a) = h(b)$, h has an interior extremum.

Interpretation: the instantaneous slope matches the secant slope at some point.

Geometry of the mean-value theorem

Recall: $\exists c \in (a, b)$ s.t.

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$

Taylor formula

Theorem (Taylor's formula of order n): Let f be $n + 1$ times differentiable on (a, b) , and let $x_0 \in (a, b)$ given. Then, for any $x \in (a, b)$, if $n = 1$,

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + \text{error}.$$

If $n \geq 2$,

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2!}(x - x_0)^2 + \frac{f^{(n)}(x_0)}{n!}(x - x_0)^n + \text{error}.$$

The error is small if x is close to x_0 , therefore, this theorem says that differentiable functions may be **locally approximated by a polynomial** called the **Taylor polynomial**.

Economics/data: local linear/quadratic approximations underlie elasticity (log-linearization), Delta method, and second-order price responses.

Taylor remainder and a handy expansion

Remainder (Lagrange form)

$$R_n^y(x) = \frac{f^{(n+1)}(y)}{(n+1)!} (x - x_0)^{n+1} \quad \text{for some } y \text{ between } x_0 \text{ and } x.$$

If $|f^{(n+1)}| \leq M$ near x_0 , then $|R_n^y(x)| \leq \frac{M}{(n+1)!} |x - x_0|^{n+1}$.

Example (log around 1): With $x_0 = 1$,

$$\log x \approx (x - 1) - \frac{1}{2}(x - 1)^2, \quad R_2^y(x) = \frac{1}{3y^3}(x - 1)^3.$$

Finance quick check: For small r , $\log(1 + r) \approx r - \frac{r^2}{2} \Rightarrow \text{EAR} \approx \text{APR} - \frac{1}{2}\text{APR}^2$ (small correction).

Short comment about small-o notation

Writing $|R_n^y(x)| \leq \frac{M}{(n+1)!} |x - x_0|^{n+1}$ we conclude $\frac{R_n^y(x)}{|x - x_0|^n} \leq \frac{M}{(n+1)!} |x - x_0|$ and so

$$\lim_{x \rightarrow x_0} \frac{R_n^y(x)}{|x - x_0|^n} = 0.$$

This we write as $R_n^y(x) = o(|x - x_0|^n)$.

In particular: If f is twice differentiable:

$$f(x+h) = f(x) + f'(x)h + o(|h|).$$

The generalization of this last expression to multivariate functions will provide powerful insights into their optimization.
